

Probability or Estimate?

Topic 4.3 · TODAY'S PROBLEM

Suppose a game uses a spinner with eight equal sectors numbered 1 through 8. A player wins when the spinner lands on 1, 2, or 3. The dotplot shows the results of 40 observed plays.

Dani: “The probability of winning is $3/8 = 0.375$ because three of the eight equally likely results win.”

Micah: “The probability is $18/40 = 0.45$ because 18 of the 40 observed plays were wins.”

FIRST TAKE (5 min, on your sheet)

Which number would you use to describe the chance of winning the next play: 0.375 or 0.45? Give one reason.

- DOK 1** (a) List the sample space and identify the outcomes in the event ‘win.’
- DOK 2** (b) Use the dotplot to verify the observed relative frequency of a win. Compute the theoretical probability under the equal-sector model, then give the difference in percentage points.
- DOK 3** (c) Under the stated equal-sector model, decide which number is the theoretical probability and which is an empirical estimate. Cite both the sample-space feature and the 40-play result, use the law of large numbers to explain why the numbers can differ, and state two features of the trial process you would check before trusting the observed proportion.
